Graphene has several peculiar properties originating from its perfect two dimensionality and from the Dirac-like nature of its charge carriers at half-filling. In particular, recent optical measurements show that at half-filling, the conductivity is essentially constant and equal, up to a few percent, to \( \sigma_0 = e^2/h \); such value only depends on the fundamental von Klitzing constant \( h/e^2 \) and not on the material parameters, like the Fermi velocity. These experimental results confirm the theoretical predictions based on the description of graphene in terms of massless non-interacting Dirac particles: lattice effects have been taken into account in recent results.

Since truly universal phenomena are quite rare in condensed matter (an example is provided by the Quantum Hall effect), it is important to understand whether this apparently universal value is just an artifact of the idealized description in terms of non-interacting fermions or rather it is a robust property still valid in the presence of electron-electron interactions, which are certainly present and expected to play a role in real graphene. This question is entirely analogous to the one concerning universality in the quantum Hall effect, a notoriously difficult and still open problem.

The effects of the electron-electron interactions on the graphene conductivity have been investigated in the Dirac approximation by perturbation theory both in the presence of long- and of short-ranged interactions; however, lowest order explicit computations have produced different results, depending on the regularization scheme (momentum cut-off or dimensional regularization) chosen to cure the spurious ultraviolet divergences introduced by the Dirac approximation. In 2005 was predicted that in the presence of electrostatic interactions the zero frequency conductivity tends to zero, while in 2006 it was argued that it converges to the free Dirac one, as a consequence of the divergence of the Fermi velocity; however, if screening or retardation effects are taken into account, the Fermi velocity is known to saturate at low frequency, in which case it is unclear what to expect. The extreme sensitivity of the conductivity to approximations or regularizations calls for a rigorous analysis.

In this paper we consider the Hubbard model on the honeycomb lattice, as a model of monolayer graphene with screened interactions. While in general the understanding of the low temperature behavior of the Hubbard model is a formidable challenge for theoreticians, in the case of the honeycomb lattice at half filling the methods introduced in and based on constructive Renormalization Group have proved to be quite effective. Using these techniques, we rigorously establish the exact (non-perturbative) vanishing of the interaction corrections to the conductivity in the zero frequency limit. All Feynman graphs contributing to the conductivity cancel out exactly in the limit, a statement analogous to the Adler-Bardeen theorem in quantum electrodynamics.

We introduce creation and annihilation fermionic operators \( \psi_+^\dagger_{\vec x,\sigma} = (a_{\vec x,\sigma}^+, b_{\vec x+\delta_1,\sigma}^+) = L^{-2} \sum_{\vec k \in B_\Lambda} \psi_+^\dagger_{\vec k,\sigma} e^{i\vec k \cdot \vec x} \) for electrons with spin index \( \sigma = \uparrow, \downarrow \) sitting at the sites of the triangular sublattices \( \Lambda_\Lambda \) and \( \Lambda_B \) of a periodic honeycomb lattice of side \( L \); we assume that \( \Lambda_A = \Lambda \) has basis vectors \( \vec l_{1,2} = \frac{1}{2}(3, \pm \sqrt{3}) \) and that \( \Lambda_B = \Lambda_A + \delta_j \), with \( \delta_1 = (1,0) \) and \( \delta_{2,3} = \frac{1}{2}(-1, \pm \sqrt{3}) \) the nearest neighbor vectors; \( \Lambda_\Lambda = \{ \vec k = n_1 \vec G_1 / L + n_2 \vec G_2 / L : 0 \leq n_i < L \} \) with \( \vec G_{1,2} = \frac{2\pi}{L}(1, \pm \sqrt{3}) \) is the first Brillouin zone (note that in the thermodynamic limit \( L^{-2} \sum_{\vec k \in B_\Lambda} \rightarrow |B|^{-1} \int d\vec k \), with \( |B| = 8\pi^2/(3\sqrt{3}) \)). The grand-canonical Hamiltonian at half-filling is \( H_0 = H_0^0 + UV_\Lambda \), where \( H_0 \) is the free Hamiltonian, describing nearest neighbor hopping \( t \) (the hopping parameter):

\[
H_0(t) = -t \sum_{\vec x \in \Lambda_\Lambda} \sum_{\sigma = \uparrow, \downarrow} \sum_{j=1,2,3} (a_{\vec x,\sigma}^+ b_{\vec x+\delta_j,\sigma} + b_{\vec x+\delta_j,\sigma}^+ a_{\vec x,\sigma}) \tag{1}
\]

and \( V_\Lambda \) is the local Hubbard interaction:

\[
V_\Lambda = \sum_{\vec x \in \Lambda_\Lambda} \prod_{\sigma = \uparrow, \downarrow} (a_{\vec x,\sigma}^+ a_{\vec x,\sigma} - \frac{1}{2}) + \sum_{\vec x \in \Lambda_\Lambda} \prod_{\sigma = \uparrow, \downarrow} (b_{\vec x,\sigma}^+ b_{\vec x,\sigma} - \frac{1}{2}) \tag{2}
\]

In order to define the lattice current and the conductivity, we modify the hopping parameter along the bond \( (\vec x, \vec x+\delta_j) \) as \( t \rightarrow t \cdot g_{\vec x,\vec x+\delta_j}(A) = t \exp(ie \int_{\vec x} A(\vec x + s\delta_j) \cdot \delta_j ds) \), where \( A(\vec x) \in \mathbb{R}^2 \) is a periodic continuum field on \( \mathcal{S}_\Lambda = \{ \vec x = L_1 \vec l_1 + L_2 \vec l_2 : \xi_i \in [0, 1) \} \); its Fourier transform is defined as \( \tilde{A}(\vec x) = |\mathcal{S}_\Lambda|^{-1} \sum_{\vec p \in \mathcal{D}_\Lambda} \tilde{A}(\vec p) e^{-i\vec p \cdot \vec x} \), where \( |\mathcal{S}_\Lambda| = \frac{2\sqrt{3}}{3} L^2 \) and \( \mathcal{D}_\Lambda = \{ \vec p = n_1 \vec G_1 / L + n_2 \vec G_2 / L : n_i \in \mathbb{Z} \} \).
\(n_2 \tilde{G}_2/L : n_i \in \mathbb{Z}\) (note that in the thermodynamic limit \(|S_0|^{-1} \sum_{\vec{p} \in D_A} \to (2\pi)^{-2} \mathcal{F}_2 \tilde{d}\)). If we denote by \(H(A) = H_0^\dagger(\{i\pi_j(\vec{A})\}) + UV\), the modified Hamiltonian with the new hopping parameters, the lattice current is defined as \(\vec{j}_I = \frac{\partial H(A)}{\partial A_I}\) which gives, at first order in \(\vec{A}\),

\[
\vec{j}_I = \vec{j}_I^{(4)} + \int \frac{d\vec{k}}{(2\pi)^3} \vec{j}_I^{(4D)} A_{\vec{k},\vec{q}},
\]

where \(\int \frac{d\vec{k}}{(2\pi)^3}\) is a shorthand for \(|S_0|^{-1} \sum_{\vec{p} \in D_A}\) and, if \(\int \frac{d\vec{k}}{(2\pi)^3}\) is a shorthand for \(L^{-2} \sum_{\vec{p} \in B_a}\) and \(\eta_\beta = \frac{1}{e^\beta - 1}\),

\[
\vec{j}_I^{(4P)} = -\text{iet} \sum_{\vec{k},\vec{q}} \frac{d\vec{k}}{2\pi} \left( a_{\vec{k}+\vec{p},\sigma}^+ b_{\vec{k}-\vec{p},\sigma}^- - e^{-i\vec{k}(\vec{\delta}_I - \delta_I)} \right)
\]

is the paramagnetic current and

\[
\frac{\left[ \vec{j}_I^{(4D)} \right]_{lm}}{\left[ \vec{j}_I^{(4)} \right]_{lm}} = e^{2i} \sum_{\vec{k},\vec{q}} \left( a_{\vec{k}+\vec{p},\sigma}^+ b_{\vec{k}-\vec{p},\sigma}^- - e^{-i\vec{k}(\vec{\delta}_I - \delta_I)} \right)
\]

is the diamagnetic tensor. The conductivity, at Matsubara frequency \(\nu_0 \in 2\pi\beta^{-1}(\mathbb{Z} + \frac{1}{2})\) and in units such that \(\hbar = 1\), is defined via Kubo formula as

\[
\sigma_{\Lambda}^{\beta,\Lambda}(\nu_0) = -\frac{K_{\Lambda}^{\beta,\Lambda}(\nu_0, \nu_0)}{\nu_0 |S_0|}
\]

where, if \(\Xi = \text{Tr}\{e^{-\beta H}\}, \langle \rangle = \Xi^{-1} \text{Tr}\{e^{-\beta H}\}\) and \(x_0 = e^{\beta H_{x0}}O e^{-\beta H_{x0}}\) for a generic operator \(O\),

\[
K_{\Lambda}^{\beta,\Lambda}(\nu_0, \nu_0) = \int dx_0 e^{-i\nu_0 x_0} \left( \langle \vec{j}_I^{(4)}(x_0, \vec{A}, t) \rangle + \langle \vec{j}_I^{(4)}(x_0, \vec{A}, t) \rangle \right)
\]

(7)

It is known that in general the interaction modifies the values of the physical quantities; for instance, the Fermi velocity \(v_F\), the wave function renormalization \(Z\) and the vertex functions are known to depend explicitly on the interaction. Moreover, it was proven in [12] that \(v_F, Z\) and the vertex functions are analytic functions of \(U\) for \(|U|\) small enough, uniformly as \(\beta, |\Lambda| \to \infty\). In this Letter we prove a similar result for the conductivity. Moreover, we prove that in the thermodynamic, zero temperature and zero frequency limit, the conductivity is universal, i.e., it is exactly independent of \(U\).

\textbf{Theorem.} There exists a constant \(U_0 > 0\) such that, for \(|U| \leq U_0\) and any fixed \(\nu_0\), \(\sigma_{\Lambda}^{\beta,\Lambda}(\nu_0)\) is analytic in \(U\) uniformly in \(\beta, \Lambda\) as \(\beta, |\Lambda| \to \infty\). Moreover,

\[
\lim_{\beta \to 0^+} \lim_{|\Lambda| \to \infty} \sigma_{\Lambda}^{\beta,\Lambda}(\nu_0) = \frac{e^2 \pi}{\hbar} \delta_{\nu_0}.
\]

Note that the limit \(\beta \to \infty\) is taken before the limit \(\nu_0 \to 0^+\). In other words, the theorem says that the interaction corrections to the conductivity are negligible at frequencies \(\beta^{-1} \ll \nu_0 \ll t\).

\textbf{Proof.} The idea of the proof is based on the two main ingredients: (i) exact lattice Ward Identities (WI) relating the current-current, vertex and 2-point functions; (ii) the fact that the interaction-dependent corrections to the Fourier transform of the current-current correlations are \textit{differentiable} with continuous derivative (in contrast, the free part is continuous and not differentiable at zero frequency). This last property follows from the non-perturbative estimates found in [12], which we now briefly recall. The generating functional for correlations can be written in terms of a Grassmann integral:

\[
e^{-W(A,\Lambda)} = \int P(d\psi) e^{V(\psi) + \psi,\Lambda + B(A,\psi)}
\]

where, if \(k = (k_0, \vec{k})\) with \(k_0\) the Matsubara frequency, \(P(d\psi)\) is the fermionic gaussian integration for \(\psi_{k,\sigma} = (a_{k,\sigma}^{\dagger}, b_{k,\sigma}^{\dagger})\), with inverse propagator

\[
g^{-1}(k) = -Z_0 \left[ \begin{array}{cc} ik_0 & \nu_0 \Omega^\dagger(\vec{k}) \\ \nu_0 \Omega(\vec{k}) & ik_0 \end{array} \right],
\]

with \(Z_0 = 1\), \(\nu_0 = \frac{3}{2} t\) and \(\Omega(\vec{k}) = \frac{2}{3} \sum_{j=1,2,3} e^{i\vec{k}(\delta_j - \vec{k})}\) (note that \(g(k)\) is singular only at the Fermi points \(k = \frac{\nu_0}{2} = \left(0, \frac{2t}{3}, \pm \frac{2\Omega(\vec{k})}{\nu_0}\right)\)). Moreover, \(B(A,\psi)\) is

\[
\int dz_0 \sum_{\vec{x},\vec{A}} \left[ -i e\psi_{x,\sigma} \left( A_0(x) 0 \right) - A_0(x + \delta_1) \psi^-_{x,\sigma} + \sum j \left( (t_{\vec{x},\vec{A}}(\vec{A}) - t) a_{(x,\vec{x} + \delta_j),\sigma}^+ b_{(x,\vec{x} + \delta_j),\sigma}^- + c.c. \right) \right]
\]

(11)

and \((\psi, \lambda) = \int dz_0 \sum_{\vec{x},\vec{A}} \left[ \psi_{x,\sigma}^{\dagger} \lambda_{x,\sigma} - \lambda_{x,\sigma}^\dagger \psi_{x,\sigma} \right]\). The response function \(K^{\beta,\Lambda}(\nu)\) corresponds to the spatial components of the tensor \(\tilde{K}_{\nu,\mu}(\nu) = \frac{\delta_{\nu,\mu}}{\nu_0} W(A,0)|_{A=0}\), with \(\mu, \nu = 0, 1, 2\). Performing the phase transformation \(\psi_{x,\sigma}^{\dagger} \to e^{i\lambda_{x,\sigma}} \psi_{x,\sigma}^{\dagger}\) in Eq. (10), we find

\[
W(\Lambda + \delta\Lambda, \Lambda e^{i\delta}) = W(\Lambda,\Lambda)
\]

(12)

which implies the following lattice Ward Identity [16]

\[
\sum_{\mu = 0}^2 p_{\mu} \tilde{K}_{\mu,\nu}(\nu) = 0,
\]

(13)

for all \(\nu \in \{0, 1, 2\}\). On the other hand, the functional integral Eq. (9) can be evaluated in terms of an exact Renormalization Group (RG) analysis, described in full detail in [12]. We decompose the field \(\psi\) as a sum of fields \(\phi^{(k)}\), living on momentum scales \(|k - k_F| \simeq 2h^2\), with \(h \leq 0\) a scale label; the tentative integration of the fields on scales \(h < h' \leq 0\) leads to an effective theory similar to Eq. (9) with a cut-off around the Fermi points of
width $2^h$ and with a scale dependent propagator $g^{(\leq h)}(k)$ with the same singularity structure as Eq. (10), with $Z_0$ and $v_0$ replaced by $Z_h$ and $v_h$, respectively (the effective wave function renormalization and Fermi velocity on scale $h$). Moreover, setting for simplicity $\lambda = 0$, at scale $h$ the interaction $V(\psi) + B(A, \psi)$ is replaced by an effective interaction $V^{(\leq h)}(\psi^{(\leq h)}) + B^{(h)}(A, \psi^{(h)})$, with the effective potential $V^{(\leq h)}(\psi^{(\leq h)})$ a sum of monomials in $\psi^{(\leq h)}$ of arbitrary order, characterized at order $n$ by kernels $W^{(h)}_{n,0}(x_1, \ldots, x_n)$ that are analytic in $U$ and decay super-polynomially in the relative distances $|x_i - x_j|$ on scale $2^{-h}$; moreover the effective source is given by

$$B^{(h)}(A, \psi) = \sum_{\mu = 0}^{2} Z_{\mu, h} \int \frac{dp}{(2\pi)^3} A_\mu(p) J_\mu(p) + B^{(h)}(14)$$

where $J_0(p) = -ie \sum f(\frac{\partial}{\partial x} + \vec{p} + \sum_{k, p, \sigma} \Gamma_0(\vec{k}, \vec{p}) \psi_{k, \sigma}$, $J_\mu(p) = -ie \sum f(\frac{\partial}{\partial x} + \vec{p} + \sum_{k, p, \sigma} \tilde{\Gamma}(\vec{k}, \vec{p}) \psi_{k, \sigma}$, $\tilde{\gamma}_\mu = \gamma_\mu \exp \{-ip_\mu \tilde{\gamma}_3\}$ and

$$\tilde{\Gamma}(\vec{k}, \vec{p}) = \frac{2}{3} \sum_3 \gamma_\sigma \eta_{\vec{k} \vec{p}} \gamma_\delta \eta_{\vec{k} \vec{p}}.$$ 

Finally, $B^{(h)}$ is a sum of monomials in $(A, \psi)$ of arbitrary order, characterized at order $n$ in $\psi$ and $m$ in $A$ by kernels $W^{(h)}_{n, m}(x_1, \ldots, x_n; y_1, \ldots, y_m)$ that are analytic in $U$, decay super-polynomially in the relative distances on scale $2^{-h}$ and are non-zero only if $m \geq 1, n \geq 0$ and $m + n \geq 3$; in particular, for all $0 < \theta < 1$, they satisfy the bounds (proved in [12]),

$$\int dx_2 \cdots dx_n dy_1 \cdots dy_m |W^{(h)}_{n, m}(x_1, \ldots, x_n; y_1, \ldots, y_m)| \leq (\text{const.}) |e|^{m(3-n-m)h} (1 - \tilde{\delta}_m, 0 + |U| 2^{0h}).$$

The bounds Eq. (10) are non-perturbative (i.e., they are based on the convergence of the expansion for the kernels $W^{(h)}$). They are obtained by exploiting the anticommutativity properties of the Grassmann variables, via a determinant expansion and the use of the Gram-Hadamard inequality for determinants, see [12]. The factor $2^{0h}$ in the bound will play a crucial role in the following and reflects the fact that the scaling dimension $3 - n - m$ is always negative for $n > 2$.

The running coupling constants $Z_h, v_h, Z_{\mu, h}$ satisfy recursive equations (beta function equations) that, due to the bound Eq. (10), lead to bounded and controlled flows, i.e., $Z(U) = \lim_{h \to -\infty} Z_h, Z_{\mu}(U) = \lim_{h \to -\infty} Z_{\mu, h}$ and $v_F(U) = \lim_{h \to -\infty} v_F(2^h)$ are analytic functions of $U$, analytically close to their unperturbed values $Z_0 = Z_{0, 0} = 1$ and $Z_{1, 0} = Z_{2, 0} = v_0 = 2^h$, see [12]. The analyticity of the kernels of the effective potential and of the $h \to -\infty$ limits of the running coupling constants implies the analyticity of the imaginary-time correlation functions (see [12]) and, similarly, the analyticity of $\sigma^{(h)}(p_0)$ claimed in the main theorem.

We are left with proving the universality result Eq. (8). To this aim, it is important to notice that $Z_h, v_h, Z_{\mu, h}$ are related by Ward Identities. Indeed, proceeding as in [13], we consider a reference model defined in a way similar to Eq. (7), with the important difference that the Grassmann integration $P(\psi)$ is modified into $P_{> h}(\psi)$, whose propagator differs from the original one by the presence of a smooth infrared cutoff selecting the momenta $\geq 2^h$; performing the phase transformation $\psi_\vec{x} \to e^{i |\vec{x}|} \psi_\vec{x}$ in this functional integral, we find the analogue of Eq. (12), which implies

$$\frac{Z_{0, h}}{Z_h} = 1 + O(U 2^{0h}), \frac{Z_{1, h}}{Z_h v_h} = \frac{Z_{2, h}}{Z_h} = 1 + O(U 2^{0h})$$

where the corrections $O(U 2^{0h})$ come from the symmetry breaking terms due to the infrared cut-off function. Therefore, the effective parameters are related by exact identities; the vertex density renormalization $Z_{(0)}^h$ is equal, up to negligible terms, to the wave function renormalization, and the current renormalization $Z_{(1)}^h$ is equal to the product of the effective velocity and the wave function renormalization $Z_{(2)}^h$.

We can write $K_{\mu, h} = K_{\mu, h}^P + K_{\mu, h}^D$, where the two terms in the right hand side correspond to the paramagnetic and diamagnetic contributions to $K_{\mu, h}$, see Eq. (7). Note that $K_{\mu, h}^D(p_0, 0)$ is independent of $p_0$; using Eq. (16), we find that $|K_{\mu, h}^D(p_0, 0)| \leq (\text{const.}) |e|^2 \sum_{h = -\infty}^{2} 2^{0h}$, which is finite. On the other hand $K_{\mu, h}^P(x) = \sum_{h = -\infty}^{2} \left[ 2 e \int_{\text{const.}}^{2} (2\pi)^3 \sum_{k, p} \Gamma^{(h)}(\vec{k}, \vec{p}) C_h(k) C_h(k + p) + H^{(h)}_{\mu, h}(x) \right]$, where the first term corresponds to the zero-th order in $U$ in renormalized perturbation theory ($F_0(k, p)$ is a suitable smooth cutoff function constraining $|k - k_F^P| + |p| \to 0$, the cutoff $k_F^P$ and $|p|$ such that $\Sigma_{h = -\infty}^{2} H^{(h)}_{\mu, h}(p, k + p) = 1$; moreover, $Z_h C^{-1}_h(k)$ is given by Eq. (11) with $Z_0, v_0$ replaced by $Z_h, v_h$) and, for all $N \geq 0$ and suitable constants $C_N$,

$$|H^{(h)}_{\mu, h}(x)| \leq C_N |U| \frac{2^{(1 + 4h)}|x|^{1}}{1 + |x|^{4}}.$$ As compared to the zero-th order contribution to $K_{\mu, h}^P$, the dimensional bound on $H^{(h)}_{\mu, h}$ has an extra factor $2^{0h}$, following again from Eq. (16). From Eq. (19),

$$|K^P_{\mu, h}(x - y)| \leq (\text{const.}) \frac{1}{1 + |x - y|^{4}},$$

that is, $K_{\mu, h}(x)$ is absolutely integrable and, therefore, its Fourier transform in the thermodynamic and zero temperature limit is continuous at $p = 0$. Combining this
remark with the WI Eq.\[13\], we find that \(\hat{K}_{\mu\nu}(0) = 0\). In fact, setting, e.g., \(p_2 = 0\), \(\hat{K}_{11}(p_0, p_1, 0) = (-p_0/p_1)\hat{K}_{01}(p_0, p_1, 0)\); taking first the limit \(p_0 \to 0\) and then \(p_1 \to 0\) in the right hand side, we get \(\hat{K}_{11}(0) = 0\); proceeding analogously, we find that \(\hat{K}_{\mu\nu}(0) = 0\) for all \(\mu, \nu \in \{0, 1, 2\}\).

On the other hand Eq.\[17\] implies that
\[
\frac{Z_{\lambda A}}{Z_{\lambda A}} = v_F(U) + O(U^{2/3}),
\]
so that \(K_{\mu\nu}^{(P)}(x) = K_{\mu\nu}^{(P,0)}(x) + K_{\mu\nu}^{(P,1)}(x)\) where \(K_{\mu\nu}^{(P,0)}(x)\) is the paramagnetic response function for the model with Hamiltonian \(H(x) = \frac{1}{2}v^2(U)\) and \(|K_{\mu\nu}^{(P,1)}(x)| \leq (\text{const.})/U(1 + |x|^{4+\theta})^{-1}\), with \(0 < \theta < 1\). Therefore, the Fourier transform of \(K_{\mu\nu}^{(P,1)}\) is differentiable in \(p\) and its derivative is continuous at \(p = 0\). A similar decomposition can be performed in the diamagnetic term, so that, defining \(K_{\mu\nu}^{(1)} = K_{\mu\nu}^{(P,1)} + K_{\mu\nu}^{(D,1)}\) and using the WI Eq.\[13\], \(\sum_{\mu=0}^2 p_\mu \hat{K}_{\mu\nu}^{(1)}(p) = 0\) from which, setting, e.g., \(p_2 = 0\), we obtain \(\hat{K}_{11}^{(1)}(p_0, p_1, 0) = (p_0/p_1)^2 \hat{K}_{00}^{(1)}(p_0, p_1, 0)\); deriving with respect to \(p_0\) both sides and taking first the limit \(p_0 \to 0\) and next \(p_1 \to 0\) in the right hand side, we get \(\partial_{p_0} \hat{K}_{11}^{(1)}(0) = 0\); proceeding analogously, we find that \(\partial_{p_\mu} \hat{K}_{\mu\nu}^{(1)}(0) = 0\) for all \(\mu, \nu \in \{0, 1, 2\}\). Note the crucial role played by the continuity of the derivatives of \(\hat{K}_{\mu\nu}^{(1)}\), which allowed us to exchange the zero frequency and zero momentum limits, as compared to the order in Eq.\[8\].

In order to compute the conductivity, we are left with the contribution associated to a free theory with Fermi velocity equal to \(v_F(U)\) that, for the 11 component, setting \(v = v_F(U)\), reads:
\[
\sigma_{11} = \lim_{p_0 \to 0^+} \lim_{\beta \to \infty} \lim_{|\Lambda| \to \infty} \sigma_{11}^{\beta, \Lambda}(p_0) = 2\epsilon^2 v^2 \int \frac{dk_0}{2\pi} \frac{1}{4} \frac{1}{\beta} \{ S(\vec{k}) - S(\vec{k} + p_0) \} \Gamma_1(\vec{k}, 0) S(\vec{k}) \Gamma_1(\vec{k}, 0). \]

The latter integral is not uniformly convergent in \(p_0\); in particular, it is well known that one cannot exchange the limit with the integral \[14\]. The integral can be evaluated explicitly (using residues to compute the integral over \(k_0\)) and leads to Eq.\[15\]. A similar computation shows that \(\sigma_{22} = \sigma_{11}\) and that the off-diagonal terms vanish. ■

The above analysis can be extended to the case of long range electromagnetic interactions; in such case the wave function, density and current renormalizations have a strong (anomalous) power law dependence on the momentum and the Fermi velocity increases up to the speed of light \[11, 13\]. Wfs similar to Eq.\[17\] are still valid and imply that, even if the effective parameters are strongly momentum dependent, the conductivity only depends weakly on the frequency in the optical range.

In conclusion, we rigorously proved the non existence of corrections to the zero temperature and zero frequency limit of the graphene conductivity due to weak short range interactions. The proof is based on a combination of constructive Renormalization Group methods with exact lattice Ward identities. Remarkably, this is one of the very few examples of universality in condensed matter that can be established on firm mathematical grounds.

A.G. and V.M. gratefully acknowledge financial support from the ERC Starting Grant CoMBoS-239694. We thank D. Haldane for valuable discussions on the role of exact lattice Ward Identities.

[17] Eq.\[17\] should be compared with the result of Theorem 2 in \[12\](b), where an unnatural definition of the currents was adopted; this led to an asymmetry \(Z_1 \neq Z_2\), which is an artifact of the unphysical definition of the currents and that, correctly, does not show up here, see \[12\](c).
